A 3-ary max heap is like a binary max heap, but instead of 2 children, nodes have 3 children. A 3-ary heap can be represented by an array as follows: The root is stored in the first location,  $a[0]$ , nodes in the next level, from left to right, is stored from  $a[1]$  to  $a[3]$ . Barrier is a synchronization construct where a set of processes synchronizes globally i.e. each process in the set arrives at the barrier and waits for all others to arrive and then all processes leave the barrier. Let the number of processes in the set be three and S be a binary semaphore with the usual P and V function. Consider the following C implementation of a barrier with line numbers shown on the left.

```
Void barrier (void) {
1      :      P(S);
2      :      process_arrived++;
3      :      V(S);
4      :      while(process_arrived!=3);
5      :      P(S);
6      :      Process_left++;
7      :      if (process_left==3)
8      :      process_arrived =0;
9      :      process_left=0;
10     :      }
11     :      V(S);
}
```

The variables `process_arrived` and `process_left` are shared among all processes and initialized to zero. In a concurrent program all three processes call the barrier function when they need to synchronize globally.

78. The above implementation of barrier is incorrect. Which one of the following is true?

  - (D) The barrier implementation is correct if there are only two processes instead of three
79. Which one of the following rectifies the problem in the implementation?
- (A) Lines 6 and 10 are simply replaced by `process_arrived-`
  - (B) At the beginning of the barrier the first process to enter the barrier waits until `process_arrived` becomes zero before proceeding to execute P(S)
  - (C) Context switch is disabled at the beginning of the barrier and re-enabled at the end
  - (D) The variable `process_left` is made private instead of shared

Consider the diagram shown below where a number of LANs are connected by (transparent) bridges. In order to avoid packets looping through circuit in the graph, the bridge organize themselves in a spanning tree. First, the root bridge is identified as the bridge with the least serial number. Next, the root bridge out (one or more) data unit units to enables the setting up of the spanning tree of shortest paths from the root bridge to each bridge. Each bridge identifies a port ( the root port) through which it will forward frames to the root bridge. Port conflict are always resolve in favour of the port with the lower index value.
